Homework 5 Chapter 10: Recursion

1.	Consider the method displayRowOfCharacters	that	displays	any	given	${\rm character}$	the	specified	${\rm number}$	of	times
	on one line. For example, the call										

displayRowOfCharacters('*', 5);

produces the line

Implement this method in Java by using recursion.

Refer to Homework5Driver.java

3. Write a method that asks the user for integer input that is between 1 and 10, inclusive. If the input is out of range, the method should recursively ask the user to enter a new input value.

Refer to Homework5Driver.java

7. (a) Write a recursive method that writes a given string backward. Consider the last character of the string first.

Refer to Homework5Driver.java

(b) Write a recursive method that writes a given string backward. Consider the first character of the string first.

Refer to Homework 5D river. java

Write two versions of a method to display a String backwards. In one version, the print statement should come before the recursive call. In the second version, the print statement should come after the recursive call. Hint: consider using a helper method for the version where the print statement comes after the recursive call.

8. A palindrome is a string that reads the same forward and backward. For example *deed* and *level* are palindromes. Write an algorithm in pseudocode that tests whether a string is a palindrome.

You must write a complete functioning method, not just pseudocode. Your method must be recursive.

Refer to Homework5Driver.java

11. Write a recursive method that counts the number of nodes in a chain of linked nodes.

Refer to Homework5Driver.java

15. Write four different recursive methods that each compute the sum of integers in an array of integers. Model your methods after the displayArray methods given in Segments 10.15 through 10.18 and described in Question 5.

You only need to write three methods.

Refer to Homework5Driver.java

17. Trace the call f(16) to the following method by showing a stack of activation records:

```
public int f(int n)
     int result = 0;
     if (n <= 4)
           result = 1;
     else
           result = f(n / 2) + f(n / 4);
     return result;
\} // end f
(a) Ø
                                                                  n
                                                                         16
                                                            (f)
                                                                  result [
                                                                         8
                                                                  n
             16
(b)
                                                                  result 1 +
      result [
                                                                         2
                                                                  result 1
             16
(c)
      result [
                                                                         16
                                                            (g)
                                                                  result [
             8
      result [
                                                                         8
                                                                  \mathbf{n}
                                                                  result 1+1
             16
(d)
                                                                         16
      result [
                                                            (h)
                                                                  result 2 +
      \mathbf{n}
      result
                                                                         16
                                                            (i)
                                                                  result 2 +
             4
      \mathbf{n}
      result | 1
                                                                  n
                                                                         4
                                                                  result 1
             16
      n
 (e)
                                                                         16
      result [
                                                            (j)
                                                                 result |2+1|
             8
      result 1 +
                                                            (k) Ø
```

18. Write a recursive algorithm in pseudocode that finds the second smallest object in a list of Comparable objects. Your method can find the second smallest number in an int[]. Your method does not have to work for a ListInterface object or any Comparable object. You can assume the array has at least two elements in it (i.e., the length ≥ 2).

Refer to Homework5Driver.java

Extra Credit

13. Consider the method contains of the class AList, as given in Segment 5.10 of Chapter 5. Write a private recursive method that contains can call, and revise the definition of contains accordingly.

Refer to AList.java

14. Repeat Exercise 13, but instead use the class LList and the method contains in Segment 7.12 of Chapter 7.

Refer to LList.java

To get extra credit for 13 and 14, you must access the underlying data structure (the array or the linked nodes) directly.

EC. Write a client-level method contains that takes a ListInterface and T object as parameters and recursively determines if the list contains the object. Do **not** invoke the contains method from the ListInterface class. The list should not be altered by the method.

In your method header, use Object instead of T. T is funky when working with static methods and I don't want you to get stuck on this, so just use Object.
